- ❑ Merging Point Algorithm
- ❑ Design Issues
- ❑ Simulation Results

Multipoint-to-Point VCs

- ❑ More than one concurrent sender
- ❑ Traffic at root
= Σ traffic originating from leaves
- ❑ Source-based fairness:
N-to-one connection = N one-to-one connections
 \Rightarrow max-min fairness among sources

VC Merging

- ❑ Buffer cells at merging point till EOM bit = 1
- ❑ Cells of senders in the same multipoint-to-point VC cannot be distinguished
- ❑ Question: Can we achieve source-based fairness?

ERICA+

- ❑ Time is slotted into averaging intervals
- ❑ ABR capacity = [link capacity – (VBR + CBR load)] × f(queue length)
- ❑ Estimate input rate = $\sum CCR_j$
- ❑ overload = input rate/ABR capacity
- ❑ ER_j_efficiency = CCR_j/overload
- ❑ ER_fairshare = ABR capacity/# of active sources
- ❑ IF overload $\leq 1 + \delta$ THEN ER_j =
 max (ER_j_efficiency, ER_fairshare, maxER_{previous})
ELSE ER_j = max(ER_j_efficiency, ER_fairshare)
- ❑ maxER_{current} = max(maxER_{current}, ER_j)
- ❑ ER in BRM_j = min(ER in BRM_j, ER_j)

Changes to ERICA+

- ❑ Remove fair share term (# active sources)
- ❑ Use CCR_{jmax} instead of CCR_j
Maximum is calculated in successive intervals
- ❑ To minimize oscillations, use exponential averaging options for:
 - Input rate
 - ABR capacity
 - $maxER_{previous}$

Rate Allocation Algorithm

1. FRM cell is received for VC j:

$CCR_j = \text{CCR from FRM}$

OR:

IF FirstFRM_j THEN

$CCR_j = \text{CCR from FRM}$

FirstFRM_j = FALSE

ELSE

$CCR_j = \max (\text{CCR from FRM}, CCR_j)$

Algorithm (Cont.)

2. BRM cell to be sent out for VC j:

IF overload $> 1 + \delta$ THEN

$$ER = CCR_j / \text{overload}$$

ELSE

$$ER = \max (CCR_j / \text{overload}, \max ER_{\text{previous}})$$

$$ER = \min (\text{capacity}, ER)$$

$$\max ER_{\text{current}} = \max (ER, \max ER_{\text{current}})$$

$$ER \text{ in BRM} = \min (ER, ER \text{ in BRM})$$

[note: $\delta = 0.1$ in our simulations]

Algorithm (Cont.)

3. End of averaging interval:

input rate = exponential average

capacity = exponential average scaled by queue function

overload = input rate/capacity

$\forall j$: FirstFRM_j = TRUE

maxER_{previous} = maxER_{current}

OR: maxER_{previous} = $(1-\alpha) \times \text{maxER}_{\text{current}} + \alpha \times \text{maxER}_{\text{previous}}$

maxER_{current} = 0

[note: $\alpha = 0.1$ in our simulations]

Merging Point Algorithm

- Maintain a bit at the merging point for each flow being merged
Bit = 1
⇒ FRM received from this flow after BRM sent to it
- BRMs are duplicated and sent to flows whose bits are set, then bits are reset

Design Issues

- ❑ Per-source accounting is avoided
- ❑ Using CCR from BRM cells can cause unfairness because CCR in BRM may belong to a source with a higher bottleneck rate than all upstream sources
- ❑ CCR from FRM cells is adequate because of $\max ER_{\text{previous}}$ term and properties of merging point
- ❑ BRM to FRM ratio at sender and inside the network is close to 1
- ❑ Destinations (not merging points) turn around BRMs for scalability, insensitivity to levels of tree and to avoid noise

Simulation Parameters

- ❑ Unidirectional traffic
- ❑ RIF = 1/32, 1
- ❑ Rule 6 disabled
- ❑ Queue control: $a = 1.15$, $b = 1$, drain limit = 50%, target queuing delay = 1.5 s
- ❑ Measurement interval = 5 ms, 200 μ s
- ❑ One cell long packets (Avoids VC merging issues)
- ❑ Max CCR and averaging maxERprevious used
- ❑ Link lengths in kms: {LINK1, LINK2, LINK3} = {50, 500, 5000}, {5000, 500, 50}

Downstream Bottleneck

- Goal: $\{S_1, S_2, S_3, S_A\} \leftarrow \{37.5, 37.5, 37.5, 37.5\}$
- ICRs: $\{S_1, S_2, S_3, S_A\} \leftarrow \{25, 25, 25, 25\}$,
 $\{100, 100, 100, 100\}, \{65, 10, 65, 10\}$
- **Result:** All sources are allocated 37.5 Mbps, small queues, LINK3 100% utilized, cells received at $dS_A : dS_1 \approx 175k : 520k \approx 1 : 3$

Upstream Bottleneck

- Goal: $\{S_1, S_2, S_3, S_4, S_A\}$
← $\{16.7, 16.7, 58.3, 58.3, 16.7\}$
- ICRs: $\{S_1, S_2, S_3, S_4, S_A\}$ ← $\{20, 20, 30, 80, 10\}$
- Results are similar with different link lengths,
RIF = 1/32, 1, interval length = 5 ms, 200 μ s (no RMs
for S_1, S_2, S_A for 4 intervals; for S_3, S_4 for 1 interval)

All links are 150 Mbps, except LINK₁ which is 50 Mbps

Simulation Results

- Upstream Bottleneck, LINK3 = 5000 km, RIF = 1, interval = 5 ms

WAN 4-leaf with upstream bottleneck: ACRs

Queue Lengths

WAN 4-leaf with upstream bottleneck

Link Utilization

WAN 4-leaf with upstream bottleneck

Cells Received

WAN 4-leaf with upstream bottleneck

Lessons Learnt

- ❑ Avoid determining the effective number of active sources
- ❑ Avoid estimation of rates of sources, or determining if a source is bottlenecked at this link
- ❑ Use only aggregate measurements
- ❑ Do not use CCR values from BRM cells
- ❑ CCR from FRM cells can be used
- ❑ Using the maximum CCR in an interval, and exponentially averaging the maximum ER in the previous interval can improve performance
- ❑ Do not turn around RM cells at merging point

Summary

- ❑ Multipoint-to-point ABR congestion control algorithms need to avoid problems that can arise in a naïve extension of point-to-point algorithms
- ❑ More extensive performance analysis is needed for proposed multipoint-to-point and multipoint-to-multipoint algorithms
